This report concerns a study which was conducted for SKB. The conclusions and viewpoints presented in the report are those of the author and do not necessarily coincide with those of the client.

Data in SKB's database can be changed for different reasons. Minor changes in SKB's database will not necessarily result in a revised report. Data revisions may also be presented as supplements, available at [www\(skb.se\)](http://www(skb.se)).

A pdf version of this document can be downloaded from [www\(skb.se\)](http://www(skb.se)).

## Abstract

In 2007 sampling of shallow ground water in water wells in soil has been performed at 12 sites within the site investigation area at Oskarshamn. The purpose of the activity is to monitor and characterise the shallow ground water in the site investigation area.

Some physical and chemical parameters were measured directly in the field but most parameters were analysed at different laboratories. The ground water sampling activity consisted of one program, chemical programme class 5 (reduced).

The large number of sites and parameters analysed have generated a large amount of data, which will later be used for advanced analysis and modelling. In this report the evaluation aims to give a simple overview of the results and to describe the quality of the data sampled 2007.

One nonconformity has occurred. Analysis of environmental metals, lanthanides and trace elements were not performed on the samples from December 2007. The reason was a mistake at the laboratory ALS. Later it was decided not to perform analysis from the archive samples.

The results showed a quite large variation between the different wells. The ion concentrations and conductivity ranged from what can be termed as low to high or very high values. The concentration of HCO<sub>3</sub> varied extensively throughout the investigation area with high concentrations in most wells. This result indicates a good ground water quality with respect to acidification at the investigated sites.

As with the ions measurements on environmental metals and trace elements varied quite much between the wells. High concentration of lead in some of the wells indicated pollution but since the concentration of lead in the wells had a similar relation to aluminium as most other elements it was argued that the high concentration of lead probably can be explained by the natural composition of minerals within the site investigation area.

The average ratios of boron (<sup>10</sup>B/<sup>11</sup>B) where similar in most wells and there seems to be low variation in the investigated area. With the exception of one site (SSM000241) the ratio of δ<sup>18</sup>O showed a good relationship with the conductivity (Figure 6-8). This result might indicate occurrence of relict seawater at the site.

The average hydrogen stable isotope ratios (δ<sup>2</sup>H) and tritium (<sup>3</sup>H) had similar values in most wells. However two wells differed with a markedly lower ratio for <sup>3</sup>H. The δ<sup>2</sup>H ratio correlates well with the δ<sup>18</sup>O ratio but the linear relation differ markedly from the “Global Meteoric Line” (δ<sup>2</sup>H=8×δ<sup>18</sup>O+10) which is based on precipitation data.

The concentration of nitrate varied with considerable higher concentration in one of the well (SSM000263). The concentration in this well can be termed as moderately high according to Swedish environmental quality criteria. This result might indicate leakage from the surrounding farmland areas. The concentration of NH<sub>4</sub>-N and PO<sub>4</sub>-P varied with markedly higher values in some of the ground water wells. The site SSM000241 differed even more with extremely high values of NH<sub>4</sub>-N and PO<sub>4</sub>-P. The concentration of carbon (TOC and DOC) varied with results between 5 and 13 mg/l in most wells. Again the well SSM000241 differed markedly with a value of 88.2 mg/l.

## Sammanfattning

Provtagning av ytligt grundvatten i jordrör har under 2007 skett vid 21 platser inom platsundersökningsområdet i Oskarshamn. Målsättningen med aktiviteten är att monitera och karakterisera det ytliga grundvattnet i området.

Några fysiska och kemiska parametrar har mätts direkt i fält men merparten av de insamlade parametrarna är resultatet av laboratorieanalyser. Aktiviteten bestod av ett program, klass 5 (reducerat).

Det stora antalet platser och analyserade parametrar har genererat en stor mängd data som senare kommer att användas för avancerad analys och modellering. I denna rapport har utvärderingen syftat till att ge en enkel översikt över resultaten och att beskriva kvaliteten av de data som samlats in 2007.

En avvikelse har identifierats. Analyser av miljömetaller, lantanoider och spårelement skedde inte på prover från december 2007. Anledningen var ett misstag på laboratoriet (ALS). Senare bestämdes det att inte utföra analyser på vatten från arkivprover.

Resultaten av undersökningarna visade på en stor variation mellan de olika grundvattenrören i området. Koncentrationen av joner och konduktivitet varierade mellan vad som kan betecknas som låga till väldigt höga värden. Likadant varierade koncentrationen av  $\text{HCO}_3^-$  mycket med höga koncentrationer vid de flesta provplatserna. Detta resultat visar på en god vattenkvalitet med avseende på försurning vid de undersökta platserna.

Liksom för jonerna varierade värdena för miljömetaller och spårelement ganska mycket mellan de olika provplatserna. En hög koncentration av bly vid några av platserna indikerade någon sorts förorening. Men eftersom relationen mellan koncentrationen av bly och aluminium liknade den som flertalet andra metaller och spårelement hade med aluminium drogs slutsatsen att resultatet med höga blyhalter kan förklaras med mineralets naturliga sammansättning i området.

Isotopkvoterna av bor ( $^{10}\text{B}/^{11}\text{B}$ ) var liknande vid de flesta provplatserna och det verkar vara en liten variation inom undersökningsområdet. Med undantag av ett jordrör, SSM000241, visade isotopen av  $\delta^{18}\text{O}$  en god relation med konduktiviteten i vattnet. Detta resultat kan indikera förekomst av relikt havsvatten vid provplatsen.

Medelvärdena av väteisotoperna deuterium ( $\delta^2\text{H}$ ) och tritium ( $\delta^3\text{H}$ ) var liknande i de flesta grundvattenrören. Resultatet från två av rören skilje sig dock med en märkbart lägre kvot för  $\delta^3\text{H}$ . Kvoterna av  $\delta^2\text{H}$  var väl korrelerade till kvoterna av  $\delta^{18}\text{O}$  men den linjära relationen skilje sig märkbart från "the Global Meteoric Line" vilken baseras på data från nederbörd.

Koncentrationen av nitrat varierade med betydligt högre värden i ett av grundvattenrören. Detta värde kan klassas som mättligt högt enligt Naturvårdsverkets kriterier. Koncentrationen av  $\text{NH}_4^-\text{-N}$  och  $\text{PO}_4^-\text{-P}$  varierade med märkbart högre halter i några av jordrören. Resultaten från jordrören SSM000241 visade på vad som kan klassas som extremt höga halter på  $\text{NH}_4^-\text{-N}$  och  $\text{PO}_4^-\text{-P}$ . Koncentrationen av kol (TOC and DOC) varierade med värden mellan 5 och 13 mg/l i de flesta jordrören. Jordrören SSM000241 hade ännu högre halt med ett värde på 88,2 mg/l.

# **1      Introduction**

This document reports the data gained by sampling of shallow ground water 2007, which is one of the activities performed within the site investigation at Oskarshamn. The work was carried out in accordance with activity plan AP PS 400-07-020. In Table 1-1 controlling documents for performing this activity are listed. The activity plan is an SKB's internal controlling document.

Within the site investigation area water has been sampled from shallow ground water wells in soil. During 2007 sampling was performed at 12 sites at four occasions (Figure 1-1). The water was analysed for a large number of parameters. All original results have been stored in the primary database SICADA. The results are traceable by the activity plan number. The data in the database will later be used for further interpretation (modelling).

**Figure 1-1.** The site investigation area and the location of the water wells in soil used for sampling of shallow ground water in 2007.

## 2 Objective and scope

The purpose of the activity was to monitor and characterise the shallow ground water in the site investigation area. According to the activity plan sampling was planned to be performed at 12 different ground water wells, at one or more occasions during 2007. One of these water wells are situated in the Ävrö, Hälö and Simpevarp peninsula area, and 11 in the Laxemar area.

Some physical and chemical parameters were measured in the field. Water samples were then taken for analysis of further parameters. The samples were later sent to different laboratories for analysis.

In general the ground water sampling activity was done according to the programme chemical class 5 (reduced). Analysed parameters are presented in Table 2-1. If it was not possible to get a sufficient amount of water for analysis of all components a priority order was set up (Table 2-1). A time schedule for the sampling in 2007 is presented in Appendix 2.

The large number of sites and parameters analysed have generated a large amount of data, which will later be used for advanced analysis and modelling. In this report the evaluation aims to give a simple overview of the results and to describe the quality of the data sampled during 2007.

**Table 2-1. Analysed components and priority order when sampling ground water wells 2007.**

Chemical programme class 5 – reduced 2007			
Components	Priority	Optional components	Priority
Alkalinity, pH, Conductivity	2	Deuterium, $\delta^{18}\text{O}$	4
Anions ( $\text{F}^-$ , $\text{Cl}^-$ , $\text{Br}^-$ , $\text{SO}_4^{2-}$ )	3	Tritium	5
Standard elements	1	$\text{Fe}^{2+}$ , Fe-tot	6
B-10	1	$\text{HS}^-$	7
Environmental metals	1	$\text{NH}_4$ , $\text{NO}_3$ , $\text{NO}_2$ , $\text{NO}_2+\text{NO}_3$ , $\text{PO}_4$	8
Lantanoïdes	1	Tot-N and Tot-P	9
Trace elements	1	DOC	10
Archive (acid rinsed)	13	TOC	11
Archive	13	POP, PON and POC	12

## **3      Equipment**

### **3.1    Equipment used in the field**

Under water pump (type 12 V Avimex) and 12 V vacuum pump. Used in the field for pumping up water from the ground water wells.

Two litres plastic cans, used in field as collecting vessels for archive samples. Acid rinsed 500 ml plastic vessels were used when sampling for analysis of Fe (II) + Fe (tot), standard elements, trace elements, lantanides, and environmental metals. Archive samples were also taken from the acid rinsed vessels.

Samples for analysis of NH<sub>4</sub>-N, NO<sub>2</sub>-N, NO<sub>3</sub>-N, NO<sub>2</sub>/NO<sub>3</sub>-N, PO<sub>4</sub>-P and DOC were filtered with disposable filters 0.45µm.

Sounding apparatus, pH-meter and thermometer were used for field measurements.

Field notes.

### **3.2    Equipment used at the laboratory**

Tube pump. Used in the laboratory to filter sampled water.

0.45 µm filter (PALL). Capsule filter used together with the tube pump.

0.45 µm membrane filter. Used together with the tube pump.

## **4 Execution**

### **4.1 Sites and sampling frequency**

The total number of sampled sites was 12 (Appendix 1). During 2007, sampling was performed at 11 sites situated in the Laxemar area and at one site (SSM000022) in the Ävrö, Hälö, and Simpevarp peninsula area (Figure 1).

The sampling frequency of the ground water wells sampled in 2007 is presented in Appendix 2. During the sampling period in March four extra water wells were sampled (SSM000260, SSM000261, SSM000262 and SSM000263).

### **4.2 Execution of sampling and treatment of samples**

To avoid contamination all sampling was conducted with protective rubber gloves and great care was taken not to contaminate containers or equipment. The day before sampling, each ground water well was visited and water was pumped out, if possible, for at least 15 minutes. On the sampling day, the ground water level was sounded and noted. Field measurements of pH were then performed, before the collecting vessels were filled with water. The samples for analysis of NH<sub>4</sub>-N, NO<sub>2</sub>-N, NO<sub>3</sub>-N, NO<sub>2</sub>/NO<sub>3</sub>-N, PO<sub>4</sub>-P and DOC were filtered in field with a syringe and 0.45 µm filters.

Bottles for most analysis were filled and treated in the field (Table 4-1). Water for archive samples, Fe (II) + Fe (tot), standard elements, trace elements, lantanoides, and environmental metals were transported in collecting vessels to a preparation room where the samples were divided into smaller bottles and treatments were made (Table 4-1). All work was conducted with protective rubber gloves to minimise the risk of contamination.

Routines for storing and delivery of samples to the different analysing laboratories are presented in Table 4-2. Some of the samples were sent immediately at the end of each day and some were stored in a refrigerator till the end of the week, when they were sent to the laboratory.

Four extra water wells were sampled in March (SSM000260, SSM000261, SSM000262 and SSM000263). Most of the parameters analysed were the same as in the regular ground water wells but some parameters differed. Analysis of δ<sup>2</sup>H, δ<sup>18</sup>O, <sup>3</sup>H, POP, PON and POC were not performed in these samples. In addition analysis of arsenic and iodine were performed.

### **4.3 Documentation**

All activities were continuously documented. Notes were taken on field conditions, time of sampling, markings of samples and so forth. Any deviations from the normal routines were also noted and commented in a special report. Delivery notes with instructions on which components to analyse were always sent with the samples to the different laboratories.

After analysis data has continuously been reported from the laboratories. As a routine a first preliminary quality control of the data was performed before storing them in the database SICADA.

## **5 Nonconformities**

Analysis of environmental metals, lantanoides and trace elements were not performed on the samples from December 2007. The reason was a mistake at the laboratory ALS. Later it was decided not to perform analysis from the archive samples.

# 6 Results

## 6.1 Primary results

All primary results from the laboratory analysis and from the field measurements are presented in Appendix 4 and 5.

## 6.2 Dissolved ions and conductivity

The concentrations of ions and the conductivity varied quite much between the sites (Table 6-1). Most of the sites with the highest concentrations of ions are situated close to the coast or under the seabed. The site SSM000042 which is situated quite far from the coast was an exception with comparably high concentrations of ions.

**Table 6-1. Average concentration of major ions and conductivity in shallow ground water wells 2007. Figures in italic indicate that some or all individual values in the calculation were below the detection limit of the analysis.**

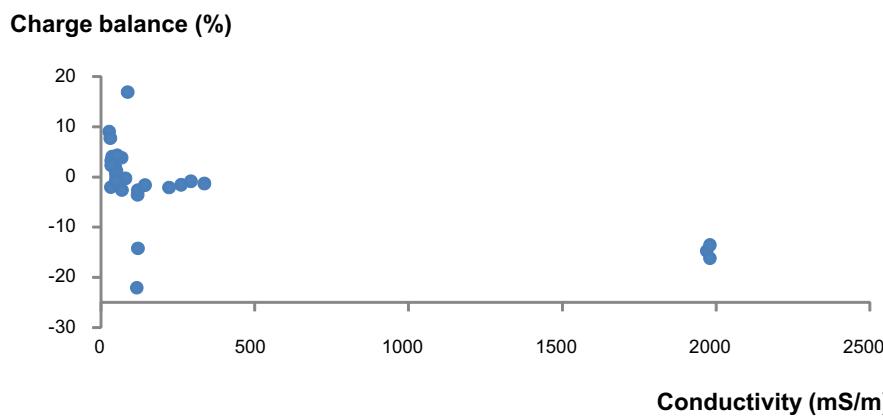

Site number	Fe (II) (mg/l)	Fe (tot) (mg/l)	Na (mg/l)	K (mg/l)	Ca (mg/l)	Mg (mg/l)	Li (mg/l)
SSM000022	0.097	0.109	204	5.42	20.5	6.23	0.029

SSM000262	152	40.5	36.3	13.0	1.69	0.224	47.5
SSM000263	135	331	58.4	20.8	1.15	0.480	143

According to the Swedish Environmental Quality Criteria /Swedish Environment Protection Agency 1999/ the concentrations of chloride ranged from low to very high at different wells, with concentrations above 100 mg/l termed as high and above 300 mg/l termed as very high.

As a quality control the charge balance has been calculated for the samples. In one of the samples there was a positive deviation of more than 10 percent (Table 6-2). This could indicate analytical problems or significant concentrations of negative ions which were not included in the calculation of the charge balance. The samples with high positive deviation in charge balance had a comparatively low conductivity though (Figure 6-1). This might be an indication of an occurrence of ions not included in the calculation of charge balance instead of analytical errors. One possible example is organic anions which has not been included in the calculations. In some cases (Table 6-2) there was a negative deviation of more than ten percent. Likewise this could indicate an analytical problem or a significant concentration of a positive ion not included in the calculation.

**Table 6-2. Samples with a charge balance which deviates more than 10 percent.**  
**Sampling in shallow ground water wells 2007.**

Site number	Sampling date	Sample number	Charge balance (%)
SSM000022	2007-03-28	11797	-14.18
SSM000022	2007-05-22	11847	16.92
SSM000042	2007-05-22	11849	-22.03
SSM000241	2007-04-04	11806	-14.70
SSM000241	2007-05-31	11904	-13.53
SSM000241	2007-09-13	15108	-16.17

**Figure 6 1.** Relation of charge balance and conductivity in samples from all ground water wells 2007.

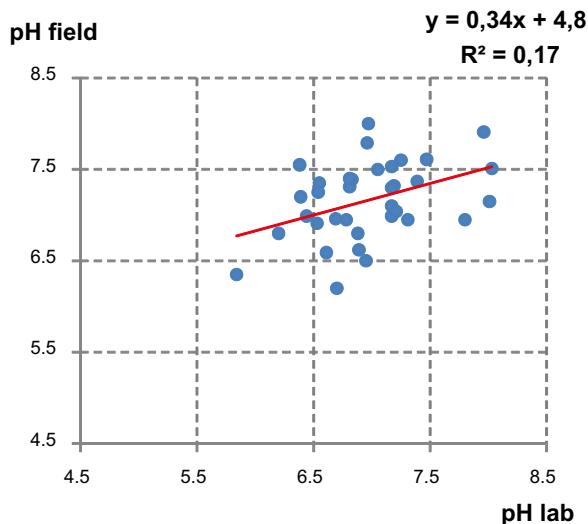

### 6.3 Acidification

As with other ions the concentration of  $\text{HCO}_3$  varied extensively throughout the investigation areas (Table 6-3). In all wells the average concentration of  $\text{HCO}_3$  was higher than 60 mg/l which is termed as a high or very high concentration according to the Swedish Environmental Quality Criteria /Swedish Environment Protection Agency 1999/. These results indicate a good ground water quality with respect to acidification at the investigated sites.

The field measurements of pH were in most cases higher than the laboratory measurements (Table 6-3 and Figure 6-2). In most ground waters the opposite is normal due to a shift in the carbonate system when the gas pressure in the water is equalised prior to the analysis in the laboratory. An explanation to the observed results might be high contents of inorganic manganese and iron which is oxidised when the water is aerated prior to the analysis.

**Table 6-3. Average concentration of  $\text{HCO}_3$ , calculated alkalinity ( $\text{HCO}_3$ ) and pH in shallow ground water wells 2007.**

Site number	$\text{HCO}_3$ (mg/l)	Alkalinity (meq/l)	pH-lab	pH-field
SSM000022	235	3.85	7.68	7.45
SSM000030	249	4.07	7.10	7.11
SSM000037	179	2.94	6.72	7.16
SSM000041	74.8	1.23	6.33	6.83

SSM000263	135	2.21	7.17	7.30

**Figure 6-2. Relation of pH measured in the laboratory and in the field in ground water wells 2007.**

## 6.4 Environmental metals and trace elements

The results of measurements on environmental metals and trace elements are presented as average concentrations in Tables 6-4 and 6-5. The results varied quite much between the wells but most elements had a strong relation with aluminium, examples are shown in Figure 6-3. This indicates a good quality of the analysis performed. However, in some cases apparent out layers exists indicating pollution, contamination or analytical errors. Two examples are Zn (SSM00041 and SSM00241, sample numbers 15104 and 11806 respectively) and Cu (SSM00263, sample number 11796) (Figure 6-4). Similar out layers exist for some elements at site SSM00241 (Figure 6-5). This ground water well seems to have a different type of water though and therefore the poor relation with aluminium is probably not an indication of pollution, contamination or analytical errors.

**Figure 6-3.** Relations between concentrations of Al and some other elements in ground water wells 2007.

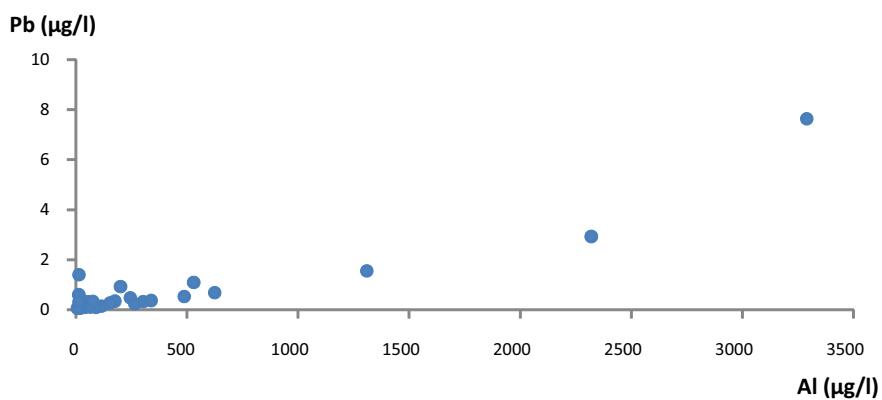

**Figure 6-4.** Relations between concentrations of Al and Cu and Al and Zn in ground water wells 2007. Apparent outliers are marked red.

**Figure 6-5.** Relations between concentrations of Al and Co and Al and Cr in ground water wells 2007. Results from SSM00241 are marked red.

Some of the environmental metals can be classified according to the Swedish Environmental Quality Criteria's /Swedish Environment Protection Agency 1999/. According to these criteria's the concentration of Cd and Zn was low to moderately high in the different wells. These results are what to be expected in an unpolluted area. However, the concentration of Pb were high ( $> 3\mu\text{g/l}$ ) in one of the wells (SSM00261) (Table 6-4b and Figure 6-6). This could be an indication of some kind of pollution. However, since the relation to aluminium is similar to most other elements the high concentration of Pb in this well can probably be explained as a natural composition of the mineral at the site.

**Figure 6-6.** Relations between concentrations of Al and Pb in ground water wells 2007.

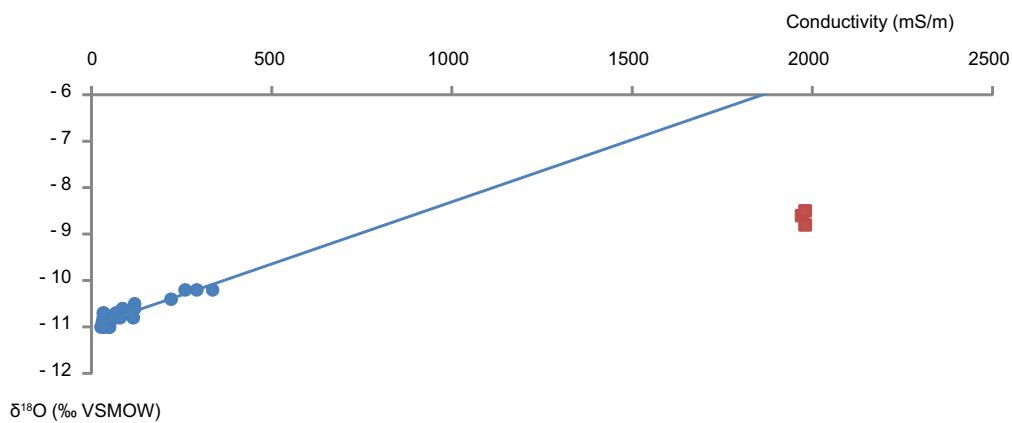

## 6.5 Isotopes

The results of the measurements of isotopes are presented in Table 6-6. The average ratios of boron ( $^{10}\text{B}/^{11}\text{B}$ ) were similar in most wells and there seems to be low variation in the investigated area. With the exception of one site (SSM000241) the ratio of  $\delta^{18}\text{O}$  showed a good relationship with the conductivity (Figure 6-7). This result might indicate occurrence of relict seawater at the site SSM000241.

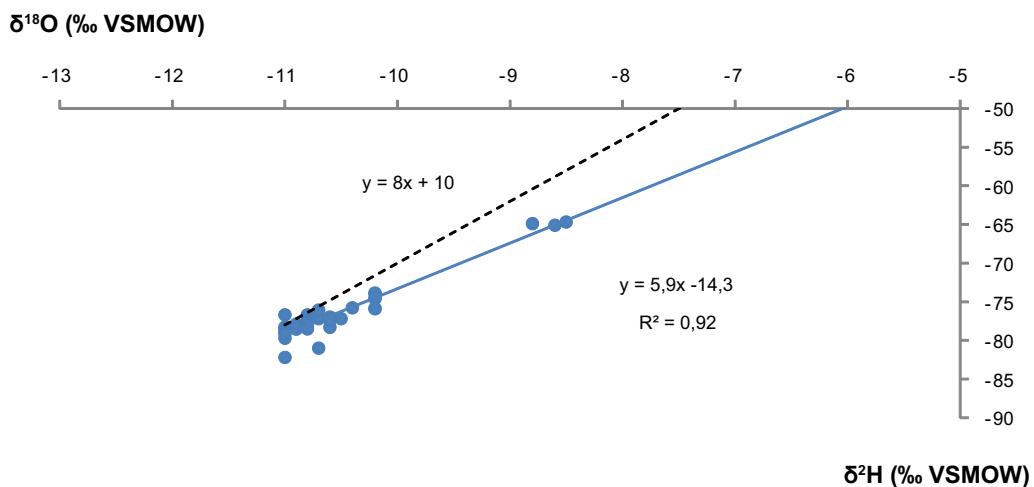

The average hydrogen isotope ratios of  $\delta^2\text{H}$  and  $\delta^3\text{H}$  had similar values in most wells. However the wells SSM000022 and SSM000241 differed with a markedly lower ratio for  $\delta^3\text{H}$ . The  $\delta^2\text{H}$  ratio correlates well with the  $\delta^{18}\text{O}$  ratio but the linear relation differ markedly from the “Global Meteoric Line” ( $\delta^2\text{H}=8\times\delta^{18}\text{O}+10$ ) which is based on precipitation data (Figure 6-8).

**Table 6-6. Average ratio of isotopes in shallow ground water wells 2007. Measurements not performed is marked with –.**

Site number	$\delta^2\text{H}$ (‰ VSMOW)	$\delta^3\text{H}$ (TU)	$\delta^{18}\text{O}$ (‰ VSMOW)	$^{10}\text{B}/^{11}\text{B}$ (atomic)
SSM000022	-77.5	1.62	-10.58	0.2332
SSM000030	-78.2	8.38	-10.90	0.2348

**Figure 6-7. The relationship between the conductivity and the ratio of  $\delta^{18}\text{O}$  in ground water wells 2007. Red dots show the site SSM000241 which had a different relationship between the conductivity and the ratio of  $\delta^{18}\text{O}$ .**

**Figure 6-8.** The local relationship between the ratios of  $\delta^2\text{H}$  and  $\delta^{18}\text{O}$  in ground water wells 2007. The dotted line shows "Global Meteoric Line" ( $\delta^2\text{H} = 8 \times \delta^{18}\text{O} + 10$ ).

## 6.6 Nutrients and carbon

The concentration of nitrate varied with considerable higher concentration in one of the well (Table 6-7). According to the Swedish Environmental Quality Criteria /Swedish Environment Protection Agency 1999/ the concentration of nitrate was moderately high (1–5 µg/l) in SSM000263. This result might indicate leakage from the surrounding farmland areas. The concentration of NH<sub>4</sub>-N and PO<sub>4</sub>-P varied with markedly higher values in some of the ground water wells. The site SSM000241 differed even more with extremely high values of NH<sub>4</sub>-N and PO<sub>4</sub>-P. The concentration of carbon (TOC and DOC) varied with results between 5 and 13 mg/l in most wells (Table 6-7). Again the well SSM000241 differed markedly with a value of 88.2 mg/l.

**Table 6-7. Average concentration of nitrogen and phosphorus compounds, and carbon in shallow ground water wells 2007. Figures in italic indicate that some individual values in the calculation were below the detection limit of the analysis. Measurements not performed is marked with –.**
