APPENDIX A2 IDENTIFIED HYDRAULIC STRUCTURES

1 INTRODUCTION

During 1996 the TRUE project will initiate detailed planning and execution of a first characterization phase for the TRUE Block Scale experiment. This initial characterization serves the purpose of finding a suitable location for the experiment. The general objectives of the TRUE Block Scale experiment can be summarized as follows (Bäckblom and Olsson 1994);

- to test numerical models and their predictive capability of radionuclide transport in a fracture network over distances 10-100 m,
- to test and evaluate scaling relationships using data from block, detailed and laboratory scales

The establishment of the experiment in the HRL is dependent not only on suitable geology and hydraulic behavior but also on the availability of locations within the HRL. Several other experiments such as the REX and TRUE-1 experiments already occupy parts of the rock volume in the vicinity to the access ramp. Further, sites for a demonstration repository and a prototype repository are in the process of being established. Also, the experimental setup of the TRUE Block Scale Experiment is not yet decided and may require certain access limitations, i.e. availability of entering the rock volume with new tunnel drifts or shafts. These limits together with the geometry of large zones intersecting the HRL constrains the location to a volume bounded by the following coordinates (Eastings, Northings); (1800,7100), (2200,7100), (2200,7450), (1800,7450) between levels (Masl) $z = -350$ to $z = -450$, Figure 1-1. In the following denoted the target volume for the TRUE Blockscales experiment.

A set of desired experimental conditions for the TRUE Block Scale Experiment have been defined (Winberg 1996). The most important ones are;

- Location outside tunnel spiral
- Size of experimental block 100x100x100m
- Location away from major fracture zones (i.e. EW-1 and NE-1)
- Access from multiple locations (vertically) in the laboratory
- No adverse hydraulic interference from other activities in the laboratory
- Transmissivity range of fractures making up the studied fracture network; $T = 5 \cdot 10^{-8} - 5 \cdot 10^{-7} \text{ m}^2/\text{s}$
- Small gradient ($I < 0.05$)
- Flow velocities such that diffusion can be a measurable process

These desired experimental conditions should be considered as guidelines, rather than absolute limitations, i.e. the selected site should qualify to as many limits as possible.

A prerequisite for updating of the conceptual model is the developed framework of major fracture zones as presented by Rhen & Stanfors (1996). However, the degree of detail in the current structural-hydraulic model has to

be increased in order to provide the necessary basis for the site selection within the target volume. Also, for selection of coming experiments in the HRL, there exists a need for enhanced detail of the conceptual model over the $z = -400$ m level.

1.2 OBJECTIVES

The objectives with this study is two-folded; the primary goal is to provide relevant data for scoping calculations of the TRUE Block Scale experiment and secondary to support future experimental localization and designs. To provide this, the following phases have been completed;

- compilation of available geological and hydrogeological information within the designated experimental volume
- evaluation and updating of the existing structural model over the level $z = -400$ Masl level in the laboratory

The process of updating the conceptual structural-hydraulic model (Rhén et al 1996), is focused primarily on the designated experimental volume. However, to increase the degree of detail of minor waterbearing structures and their material properties throughout the HRL, a first stage update is produced over the section $z = -400$ Masl. The complexity of comprehending the large amount of available data enforces us to simplify this first stage interpretation.

1.3 DISPOSITION OF THE REPORT

The main result in this report is presented in chapter 5 as quantitative tables with structural and hydraulic data for zones and rock mass. The complete report presents the process of updating as follows;

- Chapter 2 describes the boreholes and tunnel sections which penetrate the target volume and form the basis for the structural-hydraulic model update
- Chapter 3 discusses the updating of the structural model.
- Chapter 4 presents the assessment of hydraulic connectivity providing plausible conductive pathways through the target volume.
- Chapter 5 presents hydraulic head data from selected boreholes penetrating the target volume.
- Chapter 6 summarizes quantitative data for zones and rock mass in the structural-hydraulic model.
- Chapter 7 presents a discussion regarding uncertainties and proposals for future work.

1.3 COORDINATE SYSTEM AND LOCAL NORTH

In this report the coordinate system used is the Äspö local coordinate system ($X_{\text{äspö}}$) where Magnetic north (N_{Magnetic}) deviates from Äspö local north by a clockwise 12 degrees rotation. All orientation measurements presented in

Appendix A are relative to local $N_{\text{Äspö}}$. In Figures and tables with orientation relative to N_{magnetic} , extracted from existing reports, this is noted.

2 BACKGROUND DATA FOR MODEL UPDATE

Relevant data has been compiled to provide input to the updating of the structural-hydraulic model. The data are of geological and hydrogeological type and is collected from boreholes, drillcores and tunnels. This chapter presents compiled data with emphasis on the target volume, although more boreholes and tunnel sections have been reviewed in the construction of the model. Integrated presentations are given of results of performed investigations in the identified tunnel sections and boreholes in the following sections. The main results in Chapter 2 are summarized in Chapter 3 and Appendix A2.

A prerequisite for updating of the conceptual model is that the developed framework of major fracture zones, remains as presented by Rhen & Stanfors (1996).

The following parts of the tunnel system intersect the target volume;

Tunnel A (access ramp) L = 1502.5 - 1848.4 m, L = 2300.7 - 2814.0 m.

Tunnel T (TBM) L = 75.0 - 408.4 m. (3266.3 - 3599.7 m)

Tunnel F (pump pit tunnel) L = 15.0 - 75.0 m.

Tunnel H (elevator shaft) Z = -200 - -470 m.

The following core drilled boreholes intersect, or are close, to the target volume; KAS02, KAS05, KA3191F, KA2162B, KC0045F, KA2511A and KA2598A. These holes have been analyzed in a number of different projects and their structural and hydraulic results are compiled below. There are also a large number of percussion drilled bore holes of which drilling and hydraulic testing results have been utilized in the interpretation. These holes are listed in chapter 3.

Tunnel centerline and borehole coordinates are compiled and presented in Appendix A1.

2.1 BOREHOLE 2511A

This borehole was drilled as a part of a program for an experimental site selection reported by Olsson et al. (1994).

The lithology is dominated by Äspö diorite (90%) and intersected by fine-grained granite (8.5%) and greenstone (1.5%). The core log from KA2511A is shown in Figure 2-1. There are three to four sections of increased fracturing confirmed by radar and/or seismics. Figure 2-2 show identified radar and seismic reflectors respectively. The fracture orientation is generally trending NNW with an additional subhorizontal set as shown in Figures 2-3 and 2-4. A

few distinct conductive structures are identified in KA2511A with transmissivities in the range of $T = 10^{-5} - 10^{-4} \text{ m}^2/\text{s}$ as shown in Figure 2-5. Pressure build-up tests and 3 m packer tests yield a geometric mean transmissivity $T = 2.1 \cdot 10^{-7} \text{ m}^2/\text{s}$ in the tested sections in the borehole. Table 2-1 and Figure 2-6, respectively, presents the results of the 3 m packer tests in the test sections.

Table 2-2 summarizes anomalies identified in borehole KA2511A. Three locations along KA2511A can be correlated to both fracturing, seismics, radar and inflow. Two more inflows are located in fine-grained granite. Appendix A2 presents evaluated transmissivity for the five most pronounced conductive structures in KA2511A.

2.2 BOREHOLE KA2598A

This borehole was drilled as a part of a program for an experimental site selection reported by Olsson et al. (1994).

The lithology along the borehole is dominated by Småland granite (73%), Äspö diorite 15% and a larger fine-grained granite at $L = 2.4 - 47.8 \text{ m}$ (12%). In Figure 2-7, corelogging shows a section of crushed rock in a greenstone in the fine-grained granite at $L = 62 \text{ m}$. Radar and seismic indications along the borehole are illustrated in Figure 2-8 but do not correlate well. Two radar and one seismic indication, shown in Table 2-3, correlate both with increased fracturing or crushed rock and water inflow. At the two largest inflows, 13 and 18 m, no structural evidences are found. However, the inflows occur in a section of fine-grained granite with low observable fracture frequency, indicating that the fine-grained granite is highly conductive.

2.3 BOREHOLE KC0045F

This borehole was drilled as a part of a program for an experimental site selection reported by Olsson et al. (1994).

The lithology in this hole is dominated by Äspö diorite (60%) and has an unusually large content of fine-grained granite (33%). A hypothesis is that borehole KC0045F intersects a flat lying body of fine-grained granite with large subhorizontal extent. The fracture frequency, visible in the core log in Figure 2-9, is high throughout the fine-grained granite and in the lithological contacts. Radar and seismic observations, in Figure 2-10, indicate larger structures at $L = 136, 140-160, 198-207, 230-240$ and $260-265 \text{ m}$. A summary of indications in KC0045F is presented in Table 2-4.

Seven conductive structures, NNW trending, have been identified mostly by both hydraulic, structural and geophysical measurements. Appendix A2 lists the locations, known hydraulic responses and evaluated transmissivity for each

of these structures. However, the estimation of material properties may be affected by packer leakage in all sections (Olsson et al., 1994).

2.4 BOREHOLE KA2162B

The drilling and hydraulic testing in KA2162B is reported by Carlsten et al (1994) and Forsmark et al (1994).

The lithology is dominated by Småland granite (60%) where the central part intersects a 80 m wide fine-grained granite (28%). Fracture frequency, Figure 2-11, is high in the fine-grained granite, average RQD ~30, with crushed rock at lithological contacts at L = 170 and 255 m. Table 2-5 presents the pressure response observations and flow into the borehole during the drilling. There are at least three major inflow points at L = 49-53, 121 and 165-174 m. A correlation between radar, inflow and structures, Table 2-6 show a large number of structures intersecting this hole. Most of them are steep NNW trending structures. The material properties and responses from pressure build-up tests of these zones are included in Appendix A2.

2.5 BOREHOLE KAS02

The drilling and hydraulic testing in this borehole is reported by Stanfors (1988) and Rhén (1988).

The lithology in KAS02 between 300 and 500 m depth is equal amount of diorite and Äspö granite and a few sections of fine-grained granite (14%). There is increased fracturing at 315 and 370 m with radar indications at both levels. The subvertical zone interpreted to intersect KAS02 at 315 m is zone NE-2. Spinner measurements for section 309 to 318 show a transmissivity of $1.4 \cdot 10^{-5} \text{ m}^2/\text{s}$. No data is available for borehole section 370 m.

2.6 BOREHOLE KAS05

The drilling and hydraulic testing in this borehole is reported by Nilsson (1989).

The lithology in KAS05 between depth -300 to -500 masl is dominated by Äspö diorite (~80%) with few fine-grained granites. Fracture orientation is mostly subhorizontal according to Nilsson (1989). The borehole intersects a major zone at L = 310 - 337 m which may be interpreted as zone NE-2. The identified hydraulic conductors are shown in Table 2-7.

2.7 TUNNEL AND SHAFT SECTIONS

Stanfors and Rhén (1993, 1994, 1995) presented the geological compilation of tunnel and shaft data.

Compiled geological information of tunnel sections $L = 1502.5 - 1848.4$ m to $L = 2300.7 - 2814.0$ m are shown in Figures 2-12 to 2-18. Documented observations from both the TBM tunnel and the elevator shaft, below -200 masl, are shown in Figures 2-19 to 2-22. Fracture orientations are given for each tunnel leg.

In the updating process, only waterbearing fractures intersecting 75% or more of the tunnel perimeter are considered. The compilation has been focused on minor faults and zones, thus excluding the major zones. Mazurek et al (1995) compiled information of waterbearing faults and fault systems throughout the HRL. Tunnel structures included in the updating process generally follow their compilation. Figure 2-23 shows the location and spatial distribution of waterbearing faults.

3 UPDATING OF THE STRUCTURAL MODEL

To increase the degree of detail in the existing structural model, information of faults and minor zones acting as hydraulic conductors are compiled and presented in a conceptual structural model. The primary goal for the updating process has been to increase the degree of detail in the TRUE Block Scale target volume. However, an updated structural model has been produced over the whole HRL at level $z = -400$ masl. A summary of identified hydraulic structures is listed in Appendix A2.

3.1 EXISTING CONCEPTUAL STRUCTURAL MODELS

Previously, a number of different conceptual structural-hydraulic models have been published. Some of these models have been produced within specific experiments at certain localities in the HRL, others has concentrated on specific structures or zones. Stanfors & Rhén (1992 - 1996) produced and updated a site scale structural model throughout the construction phase, Figure 3-1. Winberg et al. (1996) developed several detailed structural models over specific locations along the access ramp describing minor zones and single waterbearing faults. Hermanson (1995) showed the 3D spatial variability of large waterbearing fault in the HRL.

In order to assess minor waterbearing structures a review of previously published structural and hydraulic models has been made. Where applicable, minor structures have been extracted and included in the new model, or reanalyzed with respect to its structural characteristics. However, the major zones intersecting the HRL form the framework of the updated structural model, i.e. major zones are implemented in the new model as is. The updated model only intends to increase degree of detail, not to change the foundations of the general structural model.

3.2 STRUCTURAL MODEL UPDATE

Fractures have been continuously mapped during the construction of the HRL. Most fractures tend to be non-water conducting and only approximately 10% of all mapped fractures in the tunnel are mapped to be waterbearing.

Looking at the waterbearing fracture population, only a few crosscut the whole or most of the tunnel. It is assumed that this population is true waterbearing structures extending beyond the tunnel perimeter. This assumption and this population is supported by Mazurek et al.(1996) in their selective mapping of hydraulically important minor zones and major faults along the access ramp. Most of these faults are steeply dipping or vertical with a major trend towards NW-NNW.

Note that waterbearing faults along the tunnel occur on different levels, between -230 to -470 masl, in the HRL. This implies that a true structural model needs to be in 3D rather than a 2D planar map. But the fact that these faults are mostly very steep suggest that it may be possible to visualize a structural map in one single plane. However, the major structures dip around 75° to 85° degrees which means that a lateral shift in zone intersection at depth change with as much as 50 m per 100 m elevation difference may be expected. The intersection of dipping structures is a 3D problem and can not be satisfactorily analyzed in 2D. Nevertheless, for purposes of easy understanding of the major structural trends, the interpreted possible structural-hydraulic pathways are presented in a map *in plano* at the -400 m level.

In the updating process, all cored boreholes, many percussion boreholes and selected tunnel sections in the HRL or in its vicinity have been considered, although the updating has been focused on the target volume. Following a similar approach as outlined in Chapter 2, information has been compiled from the following boreholes:

<u>Core drilled boreholes (surface)</u>	<u>Core drilled boreholes (tunnel)</u>
KAS 02	KA1751A
KAS 04	KA1754A
KAS 05	KA1755A
KAS 06	KA2048A
KAS 07	KA2162B
KAS 08	KC0045F
KAS 12	KA2511A
KAS 16	KA2512A
<u>Percussion boreholes</u>	KA2598A
HA1684B	KA2858A
HA1704B	KA2868A
HA1749A	KA3005A
HA1852A	KA3010A
HA1896A	KA3067A
HA1960A	KA3110A
HA2074A	KA3191F
HA2074B	KA3385A
HD0025A	
SA2025B	

In these boreholes, a systematical review has been performed of structural and hydraulic anomalies. Previously executed tests have been compiled into one table describing the characteristics of faults and minor structures and the evidence of their existence. Appendix A2 summarizes all structural and hydraulic evidence for the identified structures. The indications are listed by borehole, i.e. structures in a borehole are tabulated with listings of known hydraulic, geophysical or geological indications. Where interpreted, a specific zone notation has been assigned to a given structure.

The location of each hydraulic structure has been added to the structural model, and based on individual locations and orientations, interpretation of possible hydraulic pathways is suggested. Figure 3-2 show the updated structural model with interpretations of possible hydraulic pathways in the HRL on -400 masl. As most of the indications in both boreholes and tunnel are subvertical, it is possible to integrate information from many different levels in the HRL. However, the hydraulic pathways also works in 3D which makes the impression of Figure 3-2 somewhat misleading.

The structural information from boreholes and the tunnel is most often not enough to define a single structure. It is important to know that geological structures rarely occur as perfectly planar features. Faults commonly connect to each other through stepping with splay fractures forming the steps. The faults also show a wide variety of complexity along the strike. Observations in the tunnel has shown that a planar single fault observed in the tunnel may well transform into a complex fault system with lenses of good rock (Mazurek et al., 1995). Possible connectivity in the structural model is therefore illustrated as bands of possibly higher probability of having waterbearing structures.

Fault stepping may exist, with faults partly overlapping each other, and connected with each other by splay fractures and thus forming a hydraulic pathway trending 20° to 30° away from a linear projection of the fault. If fault stepping exists in a large scale, the number of possible pathways of connectivity increases dramatically. However, with no other evidence the first assumption is connectivity is highest parallel to strike rather than 20°-30° offset.

The framework of major zones constrain the projected extension of possible hydraulic pathways as they in most cases act as hydraulic boundaries. Zone NE-2 is different as it is a central zone intersecting the whole HRL. This zone is variable in width and are reported to be a m wide dry mylonite at several tunnel intersections as well as being characterized as faulted and highly conductive at others. It is one of the few structures with a NE trend and may therefore play an important role in connectivity through the HRL.

The numerous NNW trending faults in the central part of the HRL indicate the presence of the zones NNW-1 and NNW-2 c.f. Figure 3-2. The NNW trend seem to be persistent with a more or less regular interval westwards. The poorly defined zone NNW-5 is assumed to intersect KA2598A and KA2511A but is doubtful to be visible in the pit tunnel (F-tunnel) or the TBM.

The north western part of the HRL has a slight tendency of offspring structures parallel to EW-1 or NE-2 whereas the easterly part seem to have a more definite NW trend, sustained by zones NNW-4, NW-2 and NW-3.

4 ASSESSMENT OF HYDRAULIC CONNECTIVITY

Hydraulic connectivity is assessed through various hydraulic tests and activities performed in the HRL. Pressure changes caused by activities such as drilling and blasting and pump tests are regularly monitored by the Hydraulic Monitoring System, HMS. In addition portable loggers are frequently used in specific tests. In this chapter sources to analyzed pressure changes are discussed. By reviewing the pressure history of undertaken drilling and testing activities, the connectivity between borehole sections is examined. The result is presented as connectivity matrices.

4.1 DRAWDOWN EVENTS AND THEIR INTERPRETATION

The following types of possible “pressure sources” have been examined:

- tunnel excavation
- borehole drilling
- pump testing
- injection testing
- water sampling (opening valve)

The origin of pressure changes may be difficult to assess as different sources may be active simultaneously. That is, pressure changes are additive (through superposition). To increase the probability of understanding the proper connectivity a large number of different pressure change events are used in the analysis.

The problem of superposition is not the only factor that may hinder a correct interpretation of whether there exists a response between any two points. One important factor is the distance between the “pressure source” and the “receiver point” of observation. That is, the larger the distance the smaller the response and vice versa (all other factors kept constant). Other important factors are the magnitude and duration of the pressure change and any heterogeneity and/or anisotropy in the hydraulic properties (permeability and compressibility).

For a homogeneous medium the principle of reciprocity says that the test response between any two points A and B is identical regardless of which point that is acting as the source point. That is, the pressure changes at B while pumping at A are the same as the pressure changes at A while pumping at B. The principle of reciprocity is valid to all flow systems. However, in heterogeneous media, such as fracture zones, it may be difficult to validate in the field for practical reasons. For example, the hydraulic testing conducted in the SELECT programme of interference tests (Winberg et al., 1996a) shows evidence where testing at “point A” gives a response at “point B” but the reciprocity is not found when the test is reversed. This fact can in most cases be explained by the fact that the source strength (pump rate) is not equal

due to difference in transmissivity in the test sections in question and the limited duration of the tests.

Figure 4-1 shows a simple hypothetical situation which illustrates the difficulty to validate the principle of reciprocity. The figure shows a heterogeneous horizontal fracture plane intersected by two vertical boreholes, A and B. Borehole A is located in the centre of a region with low transmissivity whereas B is closer to the surrounding region where the transmissivity is much higher. The evolution in time of the response at point B while pumping at point A will be quite different from the evolution of the response at A while pumping at B (if the discharge rate is kept constant valued between the two pumping tests). While pumping at point B the region with a high transmissivity will interact at a different time and unless the discharge rate at B is increased, practically no pressure changes will be recorded at point A.

4.2 CONNECTIVITY ANALYSIS

The connectivity has been assessed through pressure monitoring during hydraulic tests or other activities in the HRL. The main objective has been to describe the general site scale pattern of connectivity. Available data are presented in three parts of the HRL: the south west corner, north east corner and the central part of the HRL. A matrix of connectivity, based on pressure disturbance from drilling, is shown in Table 4-1. Selected interference test results in the north east corner around the TRUE-1 site are presented in Table 4-2. Finally the more complex connectivity pattern in the central part of the HRL is illustrated through responses to the excavation process of the TBM tunnel, Table 4-3.

In Chapter 6, c.f. Figure 6-3, a summary of the inferred connectivity in the HRL is presented.

4.2.1 Hydraulic connectivity in the south west corner of the HRL

Zone NE-1 forms the southern hydraulic boundary in this area. Drilling of KA2511A revealed responses in KA1061A and KA1131B, c. f. Figures 4-2 and 4-3, which are located in zone NE-1 (Olsson et al., 1994). This implies connectivity between one or more structures intersecting KA2511A and NE-1. There are also pressure disturbances in SA1684B, SA1861B, Ka1751A, KA1754A and SA2338A. One possibility to explain this connection is a north easterly connector. There are three possible pathways according to the structural model; connectivity through either EW-1 or through NE-2. EW-1 is reported to be locally conductive ($T = 1.2 \cdot 10^{-5} \text{ m}^2/\text{s}$) (Rhén 1996). NE-2 intersects the south west corner, and is reported as a comparatively tight structure, $T = 1.2 \cdot 10^{-7} \text{ m}^2/\text{s}$, (Rhén 1996). Both zones seem possible as connectors.

Fracture zone NNW-5 intersects KA2511A at 53 m and KA2598A at 75 m (Stanfors 1994). Evaluated pump tests show a transmissivity of NNW-5 between $3.6 \cdot 10^{-5}$ to $1.2 \cdot 10^{-6}$ m²/s (Olsson et al., 1994). To the west of NNW-5 there are two more minor zones intersecting KA2511A. These structures also connect to NE-1, KA1751, KA1754A and SA2338A and has a transmissivity range between $T = 10^{-5}$ to 10^{-6} m²/s (Olsson et al., 1994).

In summary the south western part of the HRL appears dominated by NNW trending hydraulic conductors, comparatively isolated from each other. Although structurally a minor zone, NNW-5 and its sub parallel sister structures further west dominates the hydraulic connectivity together with either EW-1 or NE-2, or both, acting as E-W connectors.

4.2.2 Hydraulic connectivity in the north east corner of the HRL

The drilling of KA3010 caused pressure drops in the order of 40 kPa in all three sections of KA2050A, c.f. Figure 4-4. The intersected structures are interpreted as Zones NW-2 or NW-3 (Winberg 1996b). Pressure responses in the order of 80 kPa were observed during drilling of KA3067A in all sections in KA2050A, c. f. Figure 4-5. It is notable that the East-West connectivity is limited as no pressure perturbations are recorded in the otherwise highly conductive borehole KA2162B, c.f. Figure 4-6.

Drilling of KA3110A caused rapid drawdowns in test sections KA2048A:P5, (interpreted to contain NNW-4) and all three sections in KA2050A (interpreted to contain NW-2 and NW-3), c.f. Figures 4-7 and 4-8 (Winberg 1996b). The response in KA2050A is not as pronounced as the response in NNW-4 (KA2048A:5P).

Table 4-2 presents results from an extensive program of interference tests in the north eastern part of the HRL. There is reported connectivity between boreholes KA3010A, KA3068A, KA3105A and KA3110A implying NW connectivity (Winberg 1996a). However, there is also connectivity with KA2858A, KA2862A, HA1960A, KA2162B (section P3 and P4), SA2880 and SA3045. One possible pattern of connectivity is a NW-2 intersection with NNW-4 north of the spiral. NNW trending faults connected to the zone NW-2 intersect KA2162B and NNW-4, thus forming a plausible pathway of connectivity. There is also a possibility that NE-2 acts as a north easterly connector, intersecting both NW-2 and NNW-4.

The general picture of hydraulic connectivity in the north easterly part of the HRL is dominated by the three zones, NW-2 and NW-3 and NNW-4 all of which intersect this rock volume. The zones are possibly interconnected with each other either by splay faults from NW-2 (Winberg, 1996b), or by intersection of the zones to the east of the tunnel, or to the north of the tunnel. There seem to be very little connectivity to the western part of the HRL although NE-2 may work as a east-westerly conductor.

4.2.3 Hydraulic connectivity in the central part of the HRL

Investigations of the central part of the HRL show a more complex picture of connectivity. A fairly large number of waterbearing structures intersect the central part of the TBM tunnel and tunnel legs E-F, F-G and J-K. Surface investigations predicted three NNW trending zones through the spiral. The waterbearing faults in the indicated sections are interpreted as swarms rather than zones, but may well be hydraulic connectors. Boreholes KA2162B, KA3191F and KC0045A intersect this volume with almost an orthogonal angle to the dominating fracture network. KA2162B intersects a splay structure to NNW-4 at L=49-53 m which induces responses in HA1960A, SA1861B and SA1680A. Again the same responses are found at intersection L = 121 m. The latter is interpreted as part of the NNW-2 zone, although connected to NNW-4.

The drilling of the TBM pilot hole KA3191F caused responses in all four sections of KA2162B, Figure 4-9, in the order of 40 kPa. There were also responses of varying quality in KAS16:P2, SA2240B, KAS05:P3, KAS05:P2, KAS02:P3, SA2663B and SA2734A. Figure 4-10 illustrates the complex connectivity pattern when drilling through one structure in KA3191F, based on the possible pathways in the structural model.

The drilling of the TBM tunnel imposed drawdowns in large volumes of the HRL and especially in the neighboring borehole KA2162B. Drawdowns were identified in borehole KA2162B, all sections, at TBM length L = 249 m. Figures 4-11 to 4-14 and Table 4-2 summarize pressure responses in KA2162B, KA1751A, KA1754A and KA2511A due to the TBM drilling. At TBM length L=299 m there was a pressure drop in all sections in KA2511A. This is explained by a NE trending fault system through the TBM and pit pump tunnel at L = 380 m intersecting NNW-5 and its sister structures NNW-5b and NNW-5c.

Advancing with the TBM up to 350 m, KA1751A, KA1754A, KA2511A, and KA2162B are affected by the pressure disturbance. There is good connectivity in the NNW trending faults west and south of the elevator shaft, with responses in KA2162B.

In summary the connectivity in the central (and southern) part is governed by NNW to NW trending structures. NE-2 may affect the connectivity in an east-west direction, although the NE trending fault system through the TBM and pit pump tunnel may do it equally well. However, in the central part of the HRL a body of fine-grained granite found in both KC0045A and KA2162B, interpreted as a possible gently dipping sheet, may act as connector between NNW trending zones.

5 HYDRAULIC HEAD

Low hydraulic gradient is one criteria set up for selection of target volume for TRUE Block scale experiment, and can be assessed from hydraulic head measurements in sectioned-off boreholes. Hydraulic head has been calculated for HMS monitored boreholes below tunnel section L = 2000 m.

Hydraulic head for each monitored borehole section is calculated according to Rhén (1993) as follows:

$$HH = K1 + K2 \times MV$$

HH = hydraulic head (masl)

MV = pressure measured by pressure transducer

$$K1 = \frac{\rho_s g (Z_{tr} - Z_{mid}) - P_0}{\rho_0 g + Z_{mid}}$$

ρ_s = density in tube between pressure transducer and section center

g = 9.81 m/s²

Z_{tr} = level of pressure transducer (masl)

Z_{mid} = level of section centre (masl)

P_0 = normal atmospheric pressure (Pa)

ρ_0 = density of fresh water (kg/m³)

$$K2 = 1000 / (\rho_0 \times g)$$

The density ρ_s has been estimated through calculations of measured or estimated values of the electrical conductivity. Values of the electrical conductivity of Äspö water is collected from Nilsson (1995) and from Nilsson (pers. comm. 1996). In the cases of missing measurements, electrical conductivity from adjacent borehole sections have been used. The density ρ_0 has been given values according to Rhén (1993). Values of Z_{mid} have been extracted from SICADA in June 1996. Values for Z_{tr} is collected at the time of installation of the pressure transducers. Table 5-1 presents the calculated head for each monitored borehole section.

6 SUMMARY DESCRIPTION OF TARGET VOLUME MODEL

This chapter summarizes the structural-hydraulic model update. Below follows short concise descriptions and graphics of lithology, key features and quantitative tables of major fracture zones, minor fracture zones and rock mass properties.

6.1 LITHOLOGY

The lithology of the rock mass in the target volume, as shown in Figure 6-1, is dominated by Äspö diorite and intersected by dikes, strongly foliated and deformed fine-grained granite. There exists a penetrative planar foliation in the diorite, steeply dipping towards 80° NNW and locally disturbed by ductile shear or intruded fine-grained granite. The NW part of the block intersects a larger body of fine-grained granite which is highly conductive. Also, the central part of the HRL hosts a large body of fine-grained granite, interpreted to be subhorizontal. A hypothesis is that this body may be an important connector between steep NNW trending structures.

6.2 FRACTURE ZONES

The major fracture zones in the vicinity of the HRL are provided as defined by Stanfors & Rhén (1996). Table 6-1 describes the location and orientation of the major zones, here approximated to planes. Assumed extension of each zone and its interaction with other major structures is provided in Table 6-2. Interpreted hydraulic properties are presented in Table 6-3 with width estimations from borehole intersections. Table 6-4 provides transmissivity based on results from hydraulic tests and interpreted intersections of the Äspö HRL tunnel and boreholes (see also Table 6-3).

Evaluated minor fracture zones and waterbearing faults in boreholes and tunnels in the HRL are provided in Appendix A2. Identified hydraulic structures within the target volume are compiled in Table 6-5. Where possible notations are made of intercepts of identified zones.

Structurally EW-1 and NE-2 are the largest zones within the target volume. However the main trend of waterbearing faults is NW to NNW. Indications of connectivity show that NW to NNW trending structures are the main conductors (see Chapter 4) and Figure 6-2. This figure illustrates the drawdown ellipse during drilling through water conductors in KA3191F and is a representation of the general trend of connectivity in the HRL. E-W structures are reported comparatively tight (Rhén 1996), except for the southern flank of EW-1. There are a few more hydraulic indications of E-W connectivity which is attributed to the fracture network and possible interconnection between single faults. Further, the subhorizontal body of fine-grained granite is a possible connector between NW trending zones.

Although E-W connectivity exists, based on the hydraulic information from pump tests and drilling activities it appears that the SW part of the HRL is hydraulically separated from the NE part. However, the testing period of most hydraulic tests is too short to achieve steady state conditions. The understanding of tests is therefore local and does not fully reveal connectivity over longer distances.

The main identified hydraulic structures within the target volume are NNW-5c, NNW-5b, NNW-5, NNW-1, NNW-2, EW-1 and NE-2, c. f. Figure 6-3. There are more indications of hydraulic connectivity, as suggested in Figure 6-3, although not properly defined due to lack of information. Note that Figure 6-3 illustrates connectivity (blue stroked lines), as indications of most plausible pathways based on the structural model. Some lines of connectivity lack quantitative data on material properties but are inferred by responses from pump tests in boreholes in the vicinity and from waterbearing faults in the tunnel.

Identified zones not covered by table 6-1 to 6-4 is shortly described below:

- The vertical minor zone NNW-1b intersects the tunnel at $L = 1700$ m and the TBM at $L = 3355$ m and has an evaluated transmissivity $T = 0.6 \cdot 10^{-5}$ to $2.9 \cdot 10^{-5}$ m^2/s (Forsmark et al., 1994). The extent of this zone is poorly known. Its width is estimated to be at least 2 m (Mazurek et al., 1995).
- The vertical structures NNW-5b and NNW-5c are interpreted from intersections with KA2511A. NNW-5b may also intersect the end of the TBM, c.f. Figure 6-3.

The evaluated transmissivity of NNW5b and NNW-5c is $T = 2.4 \cdot 10^{-5}$ m^2/s respectively (Olsson et al., 1994). The extents of these zones are poorly known and are only documented in KA2511A as intersecting waterbearing faults.

6.3 ROCK MASS PROPERTIES

Rock mass properties are divided into fracture network properties describing fracture specific information, and hydraulic properties for rock mass units in the HRL.

6.3.1 Fracture network properties

Quantification of the fracture network of Äspö has been attempted by several authors (Dershowitz et al 1996, Follin et al 1996, Hermanson 1996, La Pointe et al 1996, Mazurek et al 1995, Poteri 1996, Uchida 1994). Dershowitz et al (1996) also incorporated borehole information from the TRUE-1 site with results from earlier investigations of the fracture network in estimating fracture network properties such as orientation, size, intensity, and spatial model.

Waterbearing fracture orientation statistics for tunnel data, presented in Table 6-6 is based on 2D and 3D trace map data from the tunnel. Three sets are defined in the fracture network, with dominance of NW trending structures. There is also a subhorizontal fracture set. This data, from the whole HRL is consistent with data from the TBM tunnel.

Fracture size is estimated through intersection statistics with the tunnel. Dershowitz et al (1996) show that depending on the methodology of mapping the results can vary, c. f. Table 6-7. However, studies by La Pointe (1995), Hermanson (1996), Follin et al., (1996) and Dershowitz et al., (1996) all show a logarithmically distributed waterbearing fracture population with arithmetic mean size of 6 m a standard deviation of 2 to 3 m.

Indications from the TRUE-1 site show that the rock mass has an intensity of conductive fractures (with transmissivity greater than 10^{-9} m²/s) of between 0.8 to 1.3 m⁻¹ for the conductive fracture intensity range of 3 to 8 m⁻¹ which provides the best fit to spinner log results. Dershowitz reports an evaluated \log_{10} mean transmissivity of -9.3 for the fracture network.

The storativity and transport aperture for fracture planes was estimated as a first approximation using the relationship derived for the LPT2 experiment (Uchida et al., 1994), i.e. $S = 0.001 T^{1/2}$ and $e = 0.5 T^{1/2}$.

6.3.2 Material properties of rock mass domains

The hydraulic conductivity of the rock mass is presented in Table 6-8 from a compilation of data from boreholes intersecting the Äspö Island. The test scale is 100 m and results are presented in 100 m sections. Results of hydraulic conductivity of the rock mass from 3 m tests in boreholes intersecting the HRL (KAS02, KAS05-08) are presented in Table 6-9.

7 CONCLUSIONS

The major hydraulic connectors in the HRL at -400 masl are NW to NNW trending zones. The connectivity in E-W direction exist but is not dominating. There are indications of low connectivity between the SW corner of the HRL and NE corner. However, connectivity is not only sustained through fracture zones. The fracture network contain waterbearing faults that may interconnect through splay fractures and thus acting at hydraulic connectors to larger NW trending zones. A large body of fine grained granite, in the central part of the HRL may also affect the E-W connectivity.

An important constraint to production of this report is the limited time available for the updating process. The updating of the structural-hydraulic model involves extensive literature surveys as the accumulated data at Äspö HRL is huge. Interpretations of structures and their hydraulic properties also change by the evolution of the HRL, making earlier work in part misleading. The large amount of pump tests, their interpretation and the assignment of the results to geological structures involve allow possibilities of error.

A thorough connectivity analysis of the fracture network at the Äspö HRL must be made in three dimensions using a computer based visualization tool. Regarding the available information on hydraulic responses, great concern must be put on quality assurance. The subjective expressions about observed hydraulic responses that are frequently used in the reporting must be revised and evaluated with regard to time, distance and heterogeneity in material properties. It is emphasised that there exists a need to assign analytical values to the often used qualifiers “great, large, good, weak, small, poor, none”.

Table 2-2 Summary of anomalies in borehole KA2511A (from Olsson et al., 1994)

Borehole length (m)	Radar indication		Seismic indication		Water inflow (l/min)	Geological indication in core
	Magn.	Dip/strike	Magn.	Dip/Strike		
25	-				30	21-23 m. Fine-grained granite
40			2	22/346		No indication (RQD = 90)
54	1	11/169	3 (51 m)	24/332	36 (53 m)	53-57 m. Fine-grained granite
58	3	76/164				Crush < 1 m. Increased fracturing
78	1	6/105	2 (83 m)	82/4		No indication
87			3	87/2		No indication
94	1	75/155				Crush < 1 m
106	1	78/153	3	27/334	24 (100 m)	103-106 m. Crush < 1 m. Increased fracturing. Fine-grained granite
121	2	71/248				122 m. Crush c 1 m
136	1	11/169	2 (132 m)	88/206		131-134 m. Fine-grained granite. Normal fracturing
150	-					149-151 m. Crush. Äspö diorite
153	-		2 (159 m)	70/164		153 m. Crush < 1 m.
185-190	-					Oxidation
199	2	68/112				198-200 m. Oxidation
214	-				24	Contact Fine-grained granite - Äspö diorite
231	2	64/264				No indication
241	1	85/111			20 (242 m)	240-243 m. Crush < 1 m
251-254	-		3 (253 m)	12/168		Greenstone. Crush 3-5 m
259	U	69/340				Crush 1 m
268	U	29/281				No indication
276-278	-		3 (275 m)	88/44		Crush < 1 m
293	1	80/265				Crush c 1 m

Table 2-3 Summary of anomalies in borehole KA2598A (from Olsson et al., 1994)

Borehole length (m)	Radar indication		Seismic indication		Water inflow (l/min)	Geological indication in core
	Magn.	Dip/strike	Magn.	Dip/Strike		
13	-				10	No indication. (RQD = 90)
18	-				12	No indication. (RQD = 90)
45	2	87/251	3 (36 m)	79/94	4 (38 m)	Alteration
			2 (40 m)	86/222		
			3 (41 m)	22/34		
50			3 (50 m)	21/62	1	Crush < 1 m
			2 (52 m)	75/106		
74	2	84/346			3	Greenstone contact. Crush 1-2 m
88			3	18/28		No indication (RQD = 100)
94					2	Oxidation
103			2	16/52		No indication (RQD = 100)
113	2	84/173				Contact f.-gr. granite - Sm. granite
136	1	55/058				Sm. granite (RQD = 75). Alteration
159	-		2 (157 m)	71/198		Crush < 1 m
			3 (165 m)	83/214		
179	1	9/319				No indication. Sm. granite. (RQD = 90)
210	2	9/258	3 (198 m)	7/222		No indication. (RQD = 80)
217	-					Crush < 1 m
226	1	37/054				Increased fracturing. Alteration
282	1	86/358				No indication. (RQD = 90-100)

Table 2-4 Summary of anomalies in borehole KC0045F (from Olsson et al., 1994)

Borehole Length (m)	Radar indication		Seismic indication		Water inflow (l/min)	Geological indication in core
	Magn.	Dip/strike	Magn.	Dip/Strike		
20	-					Crush < 1 m
32	-				15	Crush 1 m
45	2	68/321			21 (58 m)	45-60 m. Several crush c 1 m
67-72	-				24	Crush < 1 m. Increased fracturing
85	-				12	Increased fracturing
95	3	70/312			18 (94 m)	90-103 m. Increased fracturing. Several crush < 1 m
103	3	69/311			210 (99-105 m)	
119	2	12/118			145 (112-117 m)	110-115 m. Increased fracturing
127	-				18	No indications
130	2	73/288				
132	2	59/356				
136	2	61/105	2 (135 m)	85/16	18 (132-136 m)	Crush < 1 m. Increased fracturing
140-160	-		2 (144 m)	31/162	67 (142-149 m)	Several crush < 1 m. Increased fracturing. Contacts f.-gr granite - Sm. granite
172	U	20/274				Crush c 2 m
181-184	1	35/131, 88/295				Pegmatite
191	1	86/292			43 (196 m)	Increased fracturing
200	1	60/220	3 (200 m)	79/144		198-207 m. Crush 1-2 m
207	U	54/128				
215-217	-		2 (217 m)	87/342	101	No indication. RQD = 90
222			3 (221 m)	79/24	12 (223 m)	No indication. RQD = 90
231-234	1	82/300				
		85/205	1 (236 m)	76/354	582 (232-238 m)	230-240 m. Crush < 1 m. Contact greenstone - Äspö diorite. Alteration
237	2	80/137				Crush < 1 m. Alteration
246	-				250	No indication. RQD = 80-90
253	-					Crush < 1 m
262/266	1	86/292	2 (258 m)	87/326	1060 (261-267m)	260-265 m. Crush > 1 m
		75/134	2 (259 m)	3/226		
273	-				60 (273-275 m)	Increased fracturing.
286	2	79/208			138	Crush < 1 m
298	2	70/229				No indication. RQD = 80-90

Table 2-5 Pressure responses in neighboring boreholes and flow into the borehole, during drilling of KA2162B (from Forsmark et al., 1994)

A = SA1680B D = SA1861B
 B = SA1713B E = HA1960A
 C = SA1731B F = SA1997A

Depth of borehole (m)	Estimated waterflow during the drilling or from spinner surveys (l/min)	Pressure responses in borehole (m)			
		$\Delta p > 2.0$	$2.0 > \Delta p > 0.5$	$0.5 > \Delta p > 0$	$\Delta p = 0$
49 -53	375	A,D,E	F		B,C
85-91	50		A?,F		B,C,D,E
98	28				A,B,C,D,E,F
121	222	A	D	E,F	B,C
126-129	150		A?		B,C,D,E,F

Table 6-1 . Location of hydraulic conductors. The hydraulic conductors are in this table approximated to planes. Assumed extension of each plane is discussed in Table A5-5. Coordinates for zones are given in the local Äspö-system. w = waterbearing structure. p = predicted structure /Wikberg et al, 1991/. r = revised structure /Stanfors et al, 1994/. n= new structure.

Table 6-2 Deterministic hydraulic structures to be used for groundwater flow modelling. If the extension is not known of a zone at deeper levels and/or outside Äspö the zone is assumed to terminate at the model boundaries or at zones outside Äspö, if nothing else is said in the comments of the extension on the zone.

Zone	Comments on extension of the zone
EW-1N _r	This conductor explains some of the hydraulic responses in the upper part of KAS04 during some of the interference tests. The conductor is assumed to be in contact with NNW-8. Possibly there are several conductors causing the connectivity between KAS03 and KAS04 but so far it has not been possible to resolve these. The rockmass between EW-1N and EW-1S is partly low conductive perpendicular to these conductor.
EW-1S _r	This conductor explains some of the hydraulic responses in the E-W direction that was seen during the construction of the Äspö HRL. The conductors NNW-1, NNW-2 and NNW-4 are assumed to be in contact with EW-1S.
EW-3 _r	The conductor is assumed to intersect NE-2 and NE-1.
EW-7 _r	The conductor is assumed to penetrate into and terminate at NE-4 to the west.
NE-1 _r	In Table A2-4 two dips are given which more or less gives the boundaries of the conductor at approximately Z = 180 m. The direction may be approximated with the average values of X, Y and Z for NE-1, 70°NW and NE-1, 75°NW.

Table 6-2 Continued

NE-2 _r	The conductor is assumed to intersect EW-3 and all NNW structures but terminate at EW-1, 78°SE and EW-3.
NE-3 _r	In <i>Table A2-4</i> two dips are given which more or less gives the boundaries of the conductor at approximately Z = -140 m. The direction may be approximated with the average values of X, Y and Z for NE-3, 80°NW and NE-3, 70°NW.
NE-4 _r	In <i>Table A2-4</i> two dips are given which more or less gives the boundaries of the conductor at approximately Z = 110 m. The direction may be approximated with the average values of X, Y and Z for NE-4, 71°SE and NE-4, 78°SE.
NNW-1 _{wp}	The conductor is assumed to terminate to the south at EW-1N, 88°SE. This zone explains some of the hydraulic responses during some of the interference tests performed in KAS03. Possibly there are several conductors causing the connectivity between KAS03 and the percussion boreholes west of KAS03, but so far it has not been possible to resolve these. The conductor should be considered as possible.
NNW-1 _{wp}	The conductor is assumed to terminate at EW-3 and EW-1S, 78°SE.
NNW-2 _{wr}	The conductor is assumed to intersect EW-3 and terminates at NE-1 and EW-1S, 78°SE. The zone is in good contact with NE-1.
NNW-3 _{wp}	The horizontal extension is assumed to be limited by the coordinates given in <i>Table A2-4</i> . The extension towards the depth is badly known. The conductor should be considered as possible.
NNW-4 _{wr}	The conductor intersects EW-3 and NE-2 and terminate at NE-1 and EW-1, 78°SE. The zone is in good contact with NE-1.
NNW-5 _{wp}	The conductor intersects EW-3, NE-1, NE-2 and NE-3. The horizontal extension is limited to the north by the coordinates in <i>Table A2-4</i> and to the south the conductor terminates at NE-4. The conductor should be considered as possible.
NNW-6 _{wp}	The conductor is assumed to intersect NE-1, NE-3 and NE-4 and terminate at NE-1 and EW-7. The conductor should be considered as possible.
NNW-7 _{wri}	The conductor is considered possible and is assumed to terminate at EW-3 and EW-1S, 78°SE. The conductor is assumed to intersect the elevator shaft at level -185 m.
NNW-8 _{wri}	New conductor not shown on figures. This conductor explains some of the hydraulic responses during some of the interference tests in KAS03. The conductor is considered possible and terminates at EW-1N, 88°SE and about 600 m to the North of EW-1N. The conductor intersects or is close to KAS03. Possibly there are several conductors causing the connectivity between KAS03 and KAS04 but so far it has not been possible to resolve these. The extension is assumed to be approximately within the coordinates given in <i>Table A2-4</i> .

Note : Table A2-4 referenced in Table 6-2 corresponds to Table 6-1

Table 6-3 Interpreted hydrological properties of hydraulic conductors. Width estimated from mapping in the tunnel and interpreted intersections with boreholes. The value given should be considered as an approximative value. Transmissivity = T, Storativity = S, Flow porosity = n_e . Uncertain values or based on professional judgement within parenthesis.

Zone	Width (m)	T (m ² /s) $\times 10^{-5}$	S (-) $\times 10^{-5}$	n_e (%)	Comments
EW-1N _r	(30)	*	-	-	
EW-1S _r	(30)	*	-	-	
EW-3 _r	15	*	-	-	Z = 0 to -300 m. There are tests in KAS06 and in the tunnel that indicate values approximately as the given. There are geological indications that the core of the zone should be low conductive, at least partly. The transmissivity given is therefore assumed to represent the outer part of the zone.
EW-3 _r	(15)	0.05	-	-	Z < -300 m. Injection tests in KAS07 indicate low transmissivity where EW-3 is interpreted to intersect KAS07.
EW-7 _r	(10)	*	-	-	
NE-1 _r	30	*	2.6	0.7	Evaluation of a simple tracer test gave a range (depending on the concept for the flowfield) of flow porosity of 0.06 % - 2.2 %. The evaluation of spread of the grout around the tunnel gave a range of flow porosity of 0.07 % - 1 %. / <i>Rhén and Stanfors, 1993</i> /.
NE-2 _r	5	*	-	-	The zone is possibly more transmissive at levels higher than Z -250 m.
NE-3 _r	50	*	-	-	
NE-4 _r	40	*	-	-	
NW-1 _{wp}	(10)	*	-	-	
NNW-1 _{wp}	(20)	*	0.5	-	
NNW-2 _{wp}	(20)	*	0.2	0.34	Evaluation of LPT2 gave a range (depending on the concept for the flowfield) of the flow porosity of 0.02 % - 0.1 %. / <i>Rhén et al., 1992</i> /.
NNW-3 _{wp}	(20)	2	-	-

APPENDIX A2 IDENTIFIED HYDRAULIC STRUCTURES

This appendix describes identified hydraulic structures in the HRL. The header describes the location and properties of the feature as follows:

Waterbearing structure	= ID code for the structure
Zone ID	= zone of which the structure is interpreted as
Borehole ID	= borehole name
Section	= borehole length (tunnel length)
Responses & confirmation	= boreholes confirming hydraulic responses or structural evidence
TD/MI or TD/MI/PR	= Total depth/Measurement interval or Total depth/Measurement interval/Point response
Fracturing	= evidence of fracturing
Radar	= evidence of radar reflector
Seismics	= evidence of seismic reflector
Flow log	= evidence in flow log from spinner or UCM
BUP tests	= evidence from pressure build-up tests
Other tests	= interference tests (INT)
Orientation	= orientation relative to N_{asp0}
T	= Transmissivity (m^2/s)
Q	= Hydraulic conductivity (m/s)
Q/s	= Specific capacity (m^2/s)
Diffusivity	= (m^2/s)
Storativity	
Report	= Reference to the source of information

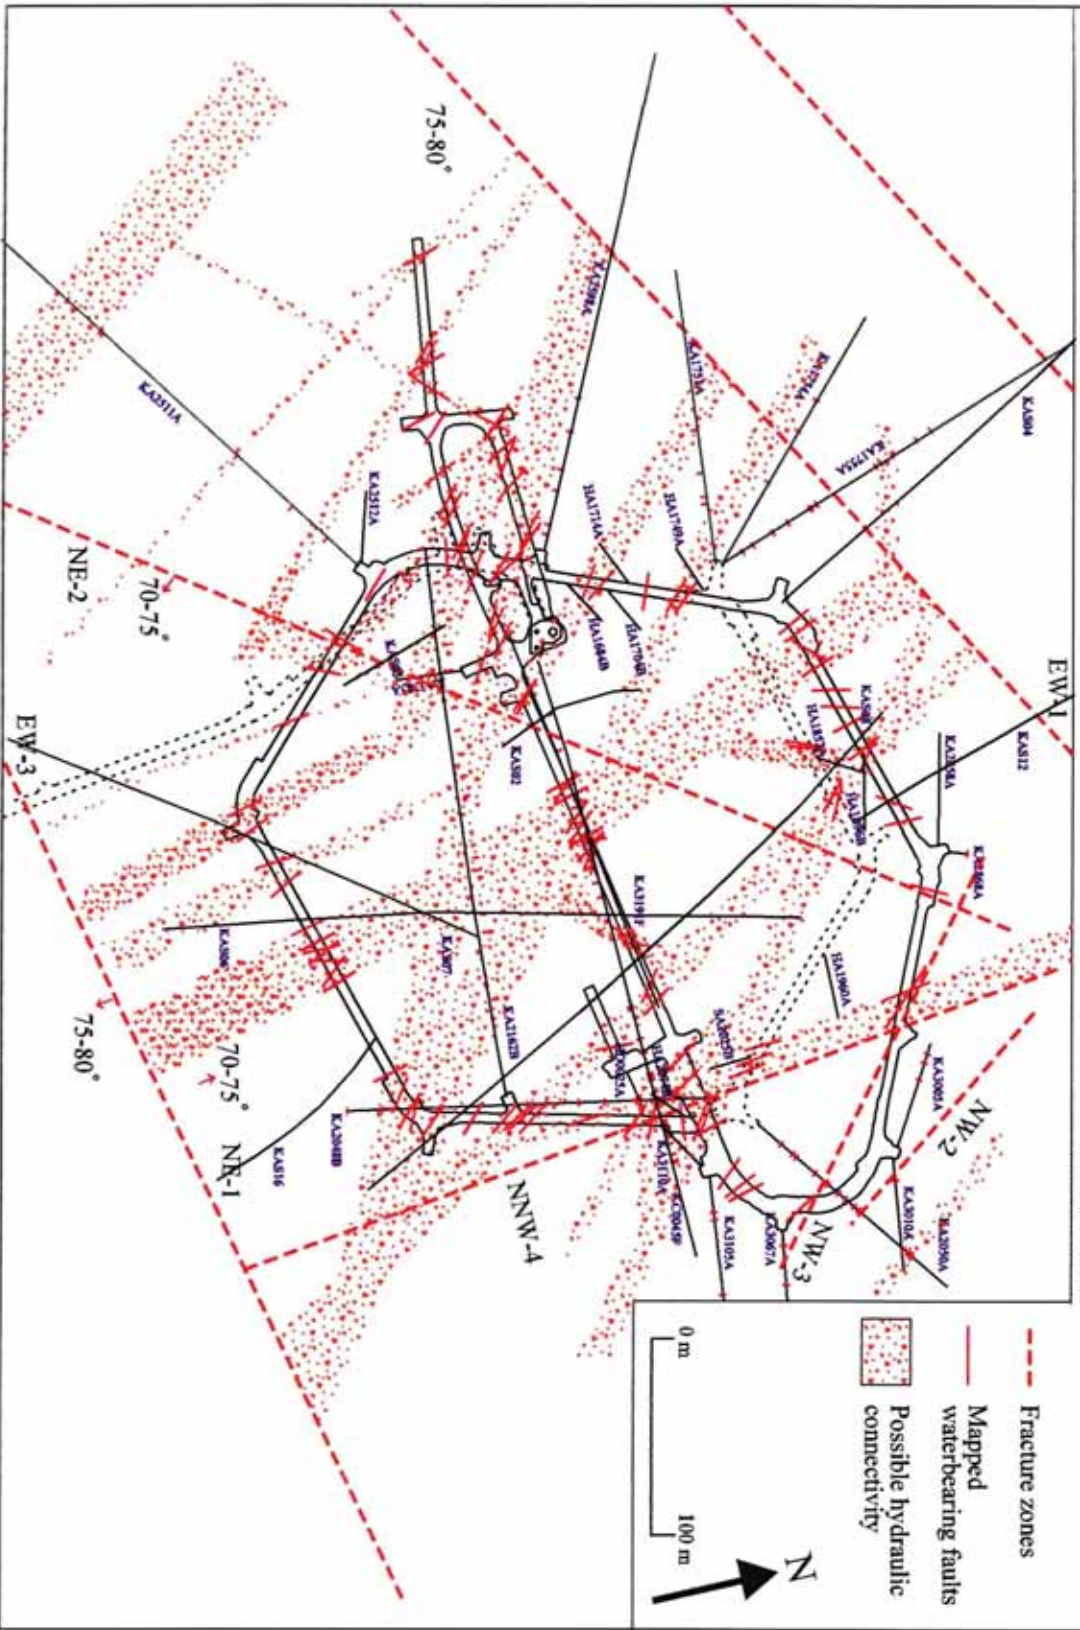

Figure 3-2 Updated structural model at Z=-400masl

Perspective View of Fracture Plane and Boreholes

Heterogeneous fracture plane. The outer region is very large and more transmissive compared to the inner region.

$$T_1 \ll T_2$$

Horizontal Section of Pressure Responses

Pressure response while
pumping at A

Pressure response while
pumping at B

Figure 4-1 A heterogeneous fracture plane intersected by two vertical boreholes, A and B. Borehole A is located in the center of a region with low transmissivity whereas borehole B is closer to the region where the transmissivity is much higher. Hydraulic testing will yield different pressure responses in the two boreholes depending on which one that is acting as source well.
